## › Key points

### Theory:

- › RFID and Bluetooth sensors *measure* proximity, which can be a proxy for the *construct* of interaction
- › But proximity is also important as a construct

### Practice:

- › Compare sensors to other data (e.g., survey data)
- › Reduce sensor data by “feature extraction” and variable selection, done with careful cross-validation

# ➤ Sensors + social network studies

# ➤ Relational sensor data

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving differing resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

# › Inconsistent terminology, confusion

## › Copenhagen Networks Study (Bluetooth):

- "Proximity data"<sup>1</sup>
- "Face-to-face interactions"<sup>2</sup>
- "Close proximity interactions"<sup>3</sup>
- "Face-to-face contacts"<sup>4</sup>
- "Physical contacts"<sup>5</sup>

## › SocioPatterns papers (RFID):

- "Person-to-person interaction"<sup>6</sup>
- "Face-to-face contacts"<sup>7</sup>
- "Close-range interactions"<sup>8</sup>
- "Face-to-face interactions"<sup>9</sup>
- "Face-to-face proximity"<sup>10</sup>

## › Audio:

- "Face-to-face conversation"<sup>11</sup>

## > Back to basics: *Constructs*.

- > *Constructs*: primitives of social science
  - A measurement might be a *proxy* for an non-observable construct (e.g., multiple choice questions and intelligence)
  - Proxies always give errors (binary construct: false negatives and false positives)
  - (Criterion-related [“predictive”] validity)
- > Face-to-face interaction: neither the measure nor the construct

# ➤ *In-person interaction* is the true construct

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving differing resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

Face-to-face proximity: false negative

Face-to-face proximity: false positive

# ➤ Constructs have their own importance

- What construct do we care about?
- Depends on what we want to study/investigate.
  - Disease transmission? Directional proximity and/or physical contact.
  - Persuasion? Conversation.
  - Mimicry? Interaction.
  - Latent homophily, expressed geographically? Proximity.
  - Environmental exposure? Proximity.

➤ Sensors +  
social  
networks

➤ Constructs vs.  
measurement

➤ Case:  
Fraternity  
cohort

➤ Resolving  
differing  
resolutions

➤ Feature  
extraction for  
social science

➤ SAOMs

➤ Ethics

➤ Summary

# › Survey data has its own importance

- › “Objective” sensor data is not superior to survey data
  - Yes, informant inaccuracy, social desirability bias, ambiguous questions...
- › But they are measuring *different things*
  - Surveys better measure the *psychological perceptions* that may ultimately be causal for behavior<sup>1</sup> (e.g., memorability<sup>2</sup>)
- › So, discrepancies must not be resolved in favor of the “objective” data
- › Discrepancies are exactly the interesting thing to study!!
- › Propinquity is an example (discrepancy is “close strangers, distant friends”<sup>3</sup>)

# ➤ Proximity is itself interesting (propinquity!)

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving differing resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

"Inferring colocation and conversation networks from privacy-sensitive audio with implications for computational social science." *ACM Transactions on Intelligent System Technologies* 2 (1), 7:1-7:41. <https://dx.doi.org/10.1145/1889681.1889688>.

# ➤ Data: Surveys + mobile phone tracking

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving differing resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

## ➤ Goal: Study propinquity

- Not proximity as proxy for interaction, but proximity itself
- Compare proximity (via “location”, WiFi) to longitudinal sociometric choice
- Look at proximity at scales larger than that of interaction
  - Small scales (proximity at  $<10\text{m}$ ): underlying causal mechanism might still be interaction.
  - Large scales (proximity  $>20\text{m}$ ): will capture other mechanisms, e.g. latent homophily, common environmental exposure, etc.

# ➤ Core problem: *Different resolutions*

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving different resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

# ➤ Approach: First do machine learning

- R.A. Fisher (1922): “The purpose of statistics is the reduction of data.”
- Step 1: Find out how to meaningfully characterize the association of proximity and friendship
- Step 2: Using this characterization, model co-evolution

Fisher, Ronald A. (1922). “On the mathematical foundations of theoretical statistics.” *Philosophical Transactions of the Royal Society of London A: Mathematical, Physical and Engineering Sciences* 222, 309–368. <https://dx.doi.org/10.1098/rsta.1922.0009>.

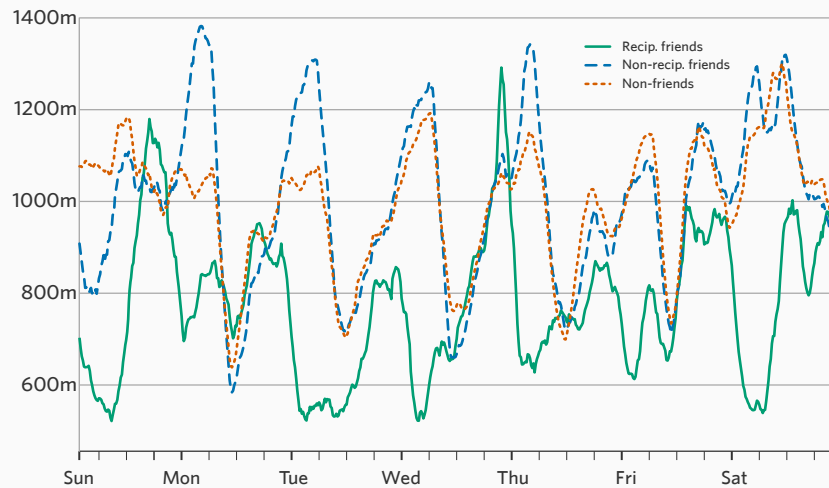

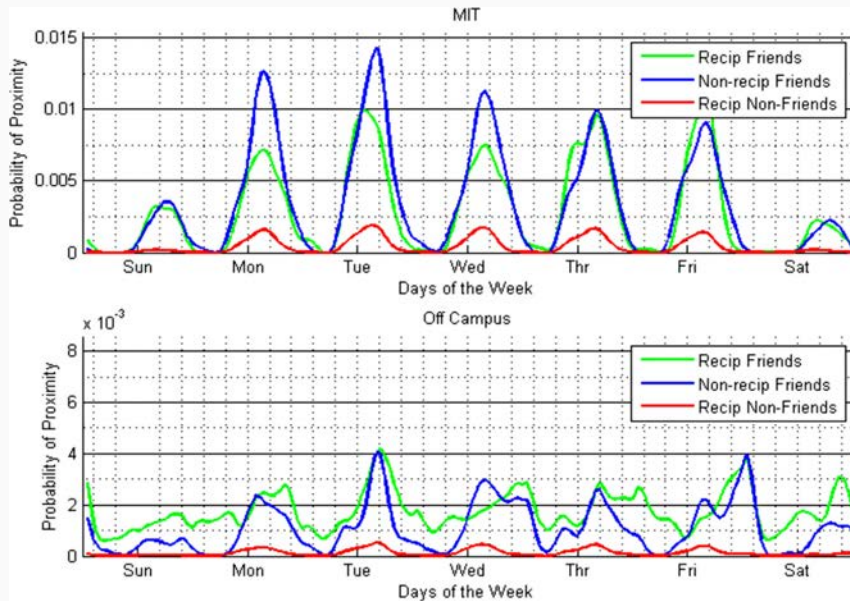

# ➤ Data processing and “feature extraction”

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving different resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

# ➤ Aggregates can mislead. Better test of an association is its predictive performance

“Probability of proximity” (Reality Mining<sup>1</sup>)    Median pairwise distance (our study)

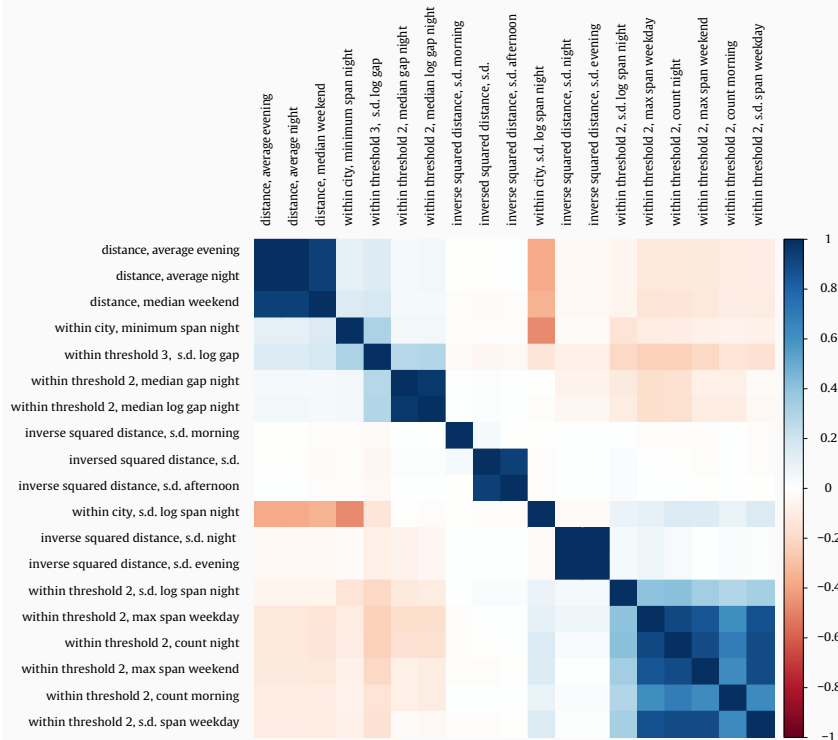

We found what looked like a compelling pattern as well, but it proved ineffective for prediction when tested with cross-validation. Why? Aggregate trends obscure between-dyad and week-to-week variance.

## ➤ Test the performance via *cross-validation*

- Split data into “training” and “test”
- Fit model on training, evaluate on test
- Done correctly, simulates out-of-sample data, thereby directly establishing external validity
- But dependencies (e.g. time, networks) can complicate cross-validation
- We use multiple cross-validation schema to control for this (details in forthcoming work)

# Result: ~30% association. Can get with 2.5K features... or 19, after feature selection.

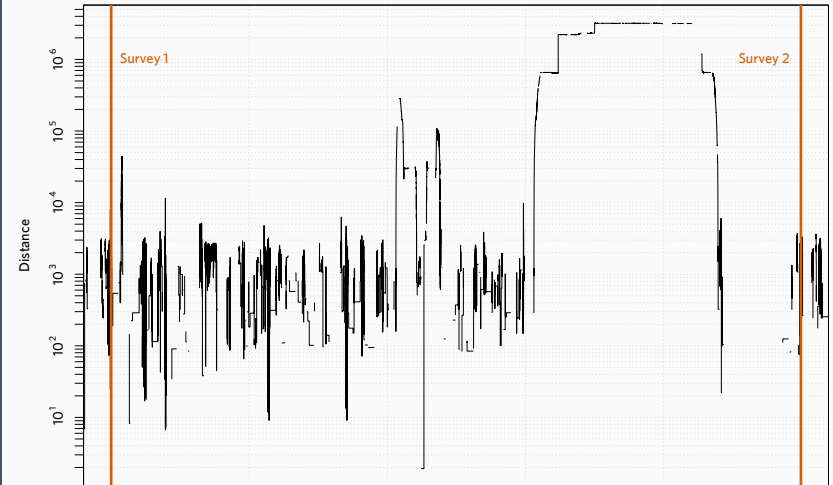

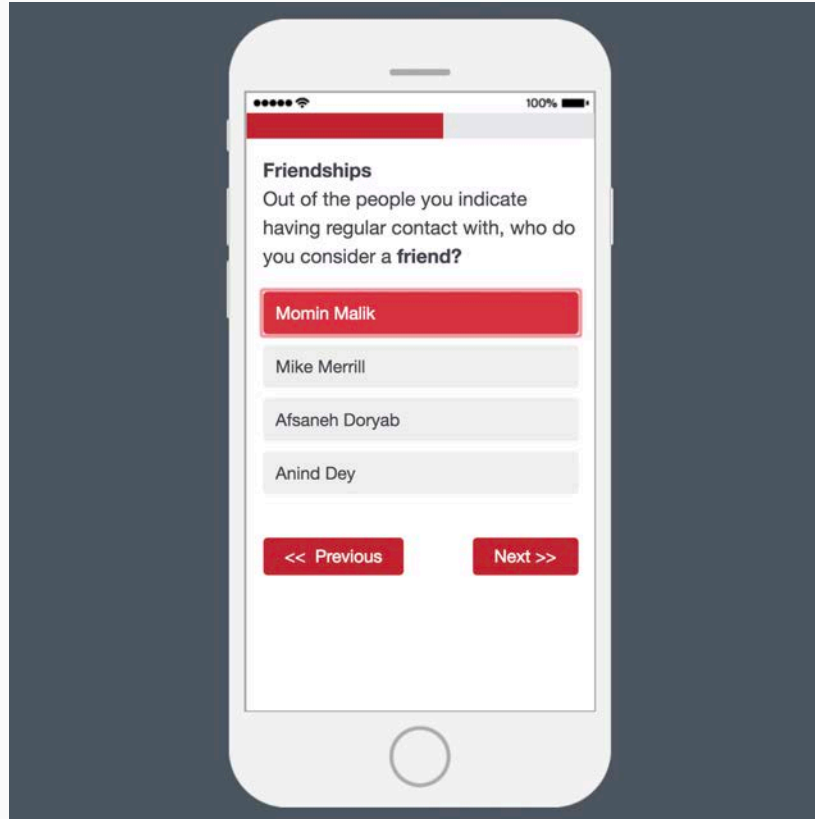

- > Sensors + social networks
- > Constructs vs. measurement
- > Case: Fraternity cohort
- > Resolving different resolutions
- > Feature extraction for social science

- > Summary

# ➤ Form of network surveys: Deliberate

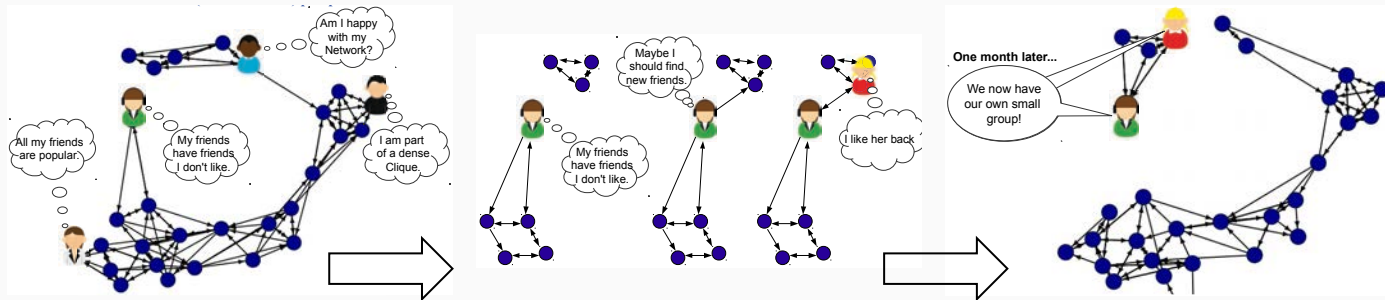

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving different resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

# ➤ Surveys based on SAOM studies

Stochastic Actor-Oriented Models (SAOMs) are the only class of models that can handle the co-evolution of network structure and behavior (they require longitudinal data)

- Combines exponential random graph models, choice models, and agent-based simulation... statistically, a doozy
- Increasing work on generalizing SAOMs, with implementations

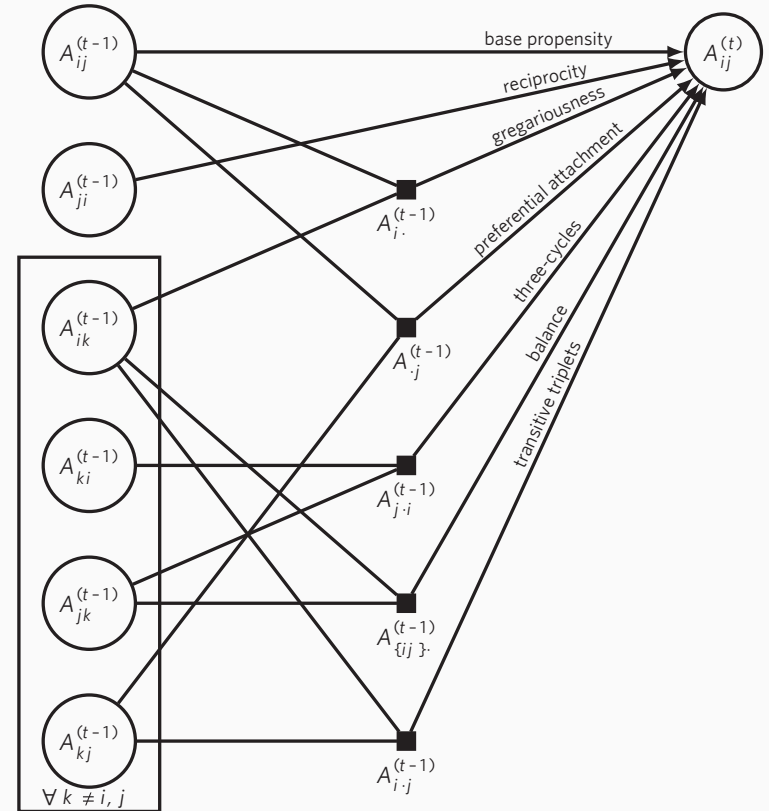

Tom A. B. Snijders, Gerhard G. van de Bunt, and Christian E. G. Steglich (2010). "Introduction to stochastic actor-based models for network dynamics." *Social Networks* 32 (1), 44-60. <https://dx.doi.org/10.1016/j.socnet.2009.02.004>.

# ➤ (Aside: SAOMs as a graphical model)

- SAOMs can relate to machine learning in another way: probabilistic graphical models
- So far, poor connections between graphical models and network models
- I am hoping this unification will help do inference

# ➤ (Proper factor graph for ERGMs)

- Sensors + social networks
- Constructs vs. measurement
- Case: Fraternity cohort
- Resolving different resolutions
- Feature extraction for social science
- SAOMs
- Ethics
- Summary

Factor graph	Parameter name	Network Motif	Parameterization	Matrix notation
	-mutual dyads		$\sum_{i < j} A_{ij} A_{ij}$	$\frac{1}{2} \text{tr}(\mathbf{AA}^T)$
	-in two stars		$\sum_{(i,j,k)} A_{ji} A_{ki}$	$\text{sum}(\mathbf{AA}^T) - \text{tr}(\mathbf{AA}^T)$

# > Ethics: Companies as foil

- > Companies are already using digital trace data—I want to know what they can and can't do
- > Debunk what they can't do, regulate what they can do
- > My study was with a non-vulnerable population. If it wasn't, I would be far more cautious
- > Who is left out is important. See Frances Cherry's (1995) critique of Festinger et al. (1950): they ignored women!

Frances Cherry (1995). "One man's social psychology is another woman's social history." In *The stubborn particulars of social psychology: Essays on the research process*, pp. 68–83. London: Routledge.

## Stop complaining about the Facebook study. It's a golden age for research

We should *insist* that Facebook do experiments on the decisions it's already making for us. Anything else would be unethical

Duncan J Watts  
theguardian.com, Monday 7 July 2014 07:45 EDT

The editor of the journal that published the Facebook study now calls it 'an important and emerging area of social science research that needs to be approached with sensitivity.' Photograph: Jeff Chiu / AP

# > Ethics of audio collection?

- > Constructs vs. measurement
- > Case: Fraternity cohort
- > Resolving different resolutions
- > Feature extraction for social science
- > SAOMs
- > Ethics
- > Summary

## › Summary: How we *should* use sensors

- › If using Bluetooth, RFID proxies for interaction, do more testing against human-coded benchmarks
- › But *proximity* (a connection of role relations and opportunity structures) is also inherently interesting
- › Compare proximity other forms of data (e.g., friendship for propinquity/influence vs. exposure)
- › Comparing sensor data and survey data, e.g. via SAOMs, is a good framework
- › Reduce/summarize rich signals through feature extraction + selection, not naïve aggregation
- › Future: use conversation add in behavioral interaction?

› Sensors + social networks

› Constructs vs. measurement

› Case: Fraternity cohort

› Resolving different resolutions

› Feature extraction for social science

› SAOMs

› Ethics

› Summary

# ➤ Thank you!

## Theory:

- RFID and Bluetooth sensors *measure* proximity, which can be a proxy for the *construct* of interaction
- But proximity is also important as a construct

## Practice:

- Compare sensors to other data (e.g., survey data)
- Reduce sensor data by “feature extraction” and variable selection, done with careful cross-validation
